

PARTNER PROGRAM APPLICATION BRIEF

PrivateDAO × MongoDB

Private decisions. Verifiable outcomes.

A concise technical and product brief describing PrivateDAO and the production Agents.PrivateDAO.org exchange, prepared for MongoDB partner-program review.

ORGANIZATION	**PrivateDAO**
PRODUCT	**PrivateDAO Agent Exchange**
PRODUCTION SURFACE	**https://agents.privatedao.org**
DOCUMENT STATUS	**Application brief • 24 September 2026**

Status note: PrivateDAO records accepted participation in the MongoDB Partner Program and MongoDB for Startups. This document describes the production integration without claiming MongoDB endorsement, certification, or joint ownership of the PrivateDAO product.

01 / EXECUTIVE SUMMARY

Executive summary

PrivateDAO is building infrastructure for agents and organizations that need confidential coordination with outcomes that can be independently verified. The production Agent Exchange at **agents.privatedao.org** exposes machine-native services for verification, evidence, repository provenance, agent workflows, and settlement-aware execution.

MongoDB Atlas is integrated as the evidence-history and search layer. When a job completes, the runtime writes an idempotent evidence document containing the job identity, service, input hash, result, completion timestamp, and provider provenance. Core job/payment state remains in DynamoDB; MongoDB is deliberately scoped to evidence history rather than custody or payment accounting.

The problem

Autonomous systems need a reliable way to coordinate actions while preserving privacy, provenance, and verifiable completion.

The product

A public, machine-native exchange where agents discover capabilities, submit structured jobs, and receive receipts with evidence hashes.

Why MongoDB

Document-shaped evidence evolves with heterogeneous agent outputs and supports indexed history/search without exposing database credentials to clients.

The opportunity

A practical technology-partner story around Atlas-powered evidence infrastructure for agentic workflows and confidential coordination.

Current public product surfaces

- A2A discovery: **https://agents.privatedao.org/a2a**
- Remote MCP: **https://agents.privatedao.org/mcp**
- Agent card: **https://agents.privatedao.org/.well-known/agent-card.json**
- Service catalog and REST API: **https://agents.privatedao.org/api/services**

PrivateDAO and Agents.PrivateDAO.org

PrivateDAO is a privacy-oriented coordination and verification product. Its public agent exchange turns capabilities into structured, discoverable services rather than opaque agent-to-agent promises. The exchange can validate inputs, execute read-only or gated actions, attach provenance, and return a machine-readable receipt.

How an agent uses the exchange

- **Discover:** read the Agent Card, service catalog, A2A surface, or MCP tools.
- **Request:** submit a structured service job with an explicit service identifier and input.
- **Execute:** run within a bounded provider boundary; paid work remains quote-first and fail-closed.
- **Evidence:** attach hashes, provider provenance, and completion metadata to the result.
- **Verify:** retrieve a receipt and use the public verification route to confirm the result.

Design principles

PRINCIPLE	IMPLEMENTATION
Privacy by boundary	Secrets remain server-side; public APIs expose sanitized provider status and receipts, not credentials.
Verifiability	Results carry deterministic hashes, provenance, timestamps, and a public receipt-verification route.
Explicit execution	Read-only capabilities are separated from job creation and payment-related actions; no automatic wallet custody.
Provider honesty	The system reports provider identity and evidence persistence status instead of implying unsupported guarantees.

03 / PRODUCTION ARCHITECTURE

Production architecture

The production service runs in AWS eu-north-1 with private network controls. MongoDB Atlas is reached through an approved service egress boundary, keeping evidence storage separate from public clients and from payment or custody responsibilities.

AGENT / CLIENT	PRIVATE DAO EDGE	DATA & PROVIDERS
MCP • A2A • REST Agent Card discovery	API Gateway Node.js 22 Lambda rate limits + gates	DynamoDB jobs, receipts, payments
Structured service request receipt retrieval	Private subnets security group: egress only Secrets Manager	MongoDB Atlas evidence history/search idempotent job index
Human or autonomous agent	Controlled egress approved Atlas access boundary	GitHub App • Solana read-only external evidence

MongoDB evidence document

Each completed job is upserted by **job_id**. The current document shape includes: **job_id**, **service**, **input_hash**, **completed_at**, **result**, **provider**, and **updated_at**. The runtime creates a unique job index and a service/time index for history queries. This makes retries safe and keeps the evidence layer useful across heterogeneous service results.

Boundary of responsibility

MongoDB does not hold wallet keys, seed phrases, GitHub App private keys, or client credentials. DynamoDB remains the canonical operational store for job, quote, receipt, and payment records; MongoDB provides the searchable evidence-history projection.

04 / PRODUCTION VERIFICATION

Production verification

The following evidence was captured from the live production surface on 24 September 2026. The validation used a free verification workflow, so a partner or customer payment was not required to confirm the production integration.

CHECK	RESULT	EVIDENCE
Public health	PASS	status=ok; network=solana-mainnet-beta
Provider status	PASS	MongoDB configured; role=evidence-history-and-search; credentials_exposed=false
Production job	PASS	job_15950ed5-3c68-4db3-8c99-c41ce7ffa654
MongoDB write	PASS	result.evidence_persistence=persisted
MongoDB direct read	PASS	found=true; provider=mongodb; service=verify.basic
Receipt	PASS	rvr_4c40eed6ea561454cbdd8dcaaabc7a72; status=VERIFIED
Receipt verification	PASS	HTTP 200 at /verify/receipt/{receipt_id}

Operational posture

- MongoDB credentials are read from AWS Secrets Manager and never returned by public provider status.
- Atlas access is restricted to the approved production egress boundary; temporary local verification access was removed after testing.
- MongoDB connection failure is surfaced as evidence_persistence=unavailable rather than hidden or treated as success.
- The integration is read/write for evidence persistence only; no payment or wallet custody is delegated to MongoDB.

Business case and partner relationship

Organizations are adopting autonomous software to research, coordinate and act, but they still need a dependable record of what happened. PrivateDAO turns agent activity into evidence that teams can review, search and verify without exposing sensitive operational details.

The customer value

- Teams receive a clear, searchable history of agent work instead of fragmented logs and unverifiable claims.
- Sensitive workflows can remain private while outcomes remain accountable to operators, reviewers and partners.
- Agents can use one discoverable exchange for verification, intelligence and workflow services with consistent receipts.
- The model supports a practical path from pilot projects to repeatable enterprise operations.

Why MongoDB is relevant

MongoDB Atlas gives this customer story a flexible evidence-history layer for varied agent outputs, searchable operational history and future tenant-aware analytics. PrivateDAO participates in the MongoDB Partner Program and MongoDB for Startups, with program benefits and commercial terms governed by the applicable MongoDB agreements.
